1 Guide to Running E3-India

1.1 Getting started

This chapter describes the steps required to install and run the model. We start with a general overview in this section and then describe how to run the model using the graphical interface. The model itself and the graphical interface come as a single package and are designed specifically to work together.

Installation E3-India is set up to run on a PC running Windows version 8 or higher¹. There are otherwise no specific computer requirements but the software works best in Google Chrome, and we highly recommend using Chrome as a platform for the software. The model has also been tested in Microsoft Edge but it does not operate in older versions of Internet Explorer. The model works in Windows but at present it does not work on Mac computers.

The Manager software is provided as part of a package for the E3-India model. It collates all E3-India model inputs into one place, enabling users to make changes directly to the input files or to load files that have been edited elsewhere (e.g. using other text editor software) and viewing the model results.

Getting started To get started:

- 1. Download the software to the directory C:\E3-India on your local drive.
- 2. In the C:\E3-India\ directory, launch the shortcut *manager.exe* (full path C:\E3-India\Manager\).

This will launch the E3-India Model Manager software in your default internet browser. The link may be copied into another browser window, so it is not necessary to set Chrome as your default browser.

1.2 The E3-India Manager interface

The Manager software collates all E3-India model inputs into one place, enabling users to make changes directly to the input files or to load files that have been edited elsewhere. It is also used for viewing the model results.

¹ Most of the testing has been carried out using Windows 10.

Figure 1.1 shows an image of the software on start-up.

Figure 1.1: Image of the software on start-up

The software contains seven main tabs, which are described in Table 1.1. Many of the tabs link to other files that are installed on your local drive.

Table 1.1: The main tabs in the Manager

| Tab: | Description: |
|---|--|
| Instructions (original files in c:\e3- india\In\) | The instructions files include the commands to set up and run the model (see below). More complex scenarios can be assessed by modifying the instructions files. On installation, E3-India has a pre- loaded set of files. There are further options to modify, duplicate and delete files. |
| Scenarios (original files in c:\e3- india\In\Scenario\) | The scenario files include a set of policy options that can be entered directly in the Manager. On installation, there is a baseline option and some test cases. Modifications can be made here. |
| Assumptions (original files in c:\e3- india\In\Asns\) | The assumptions file includes a set of forward-looking assumptions that are necessary for the model to run. These assumptions can be modified here. |
| Variables | A list of the main E3-India variables for reference. |
| Running the model | Here the user can set up and run the model, entering the choice of scenario and assumption input files and choosing a name for the output file. |
| Model results | This tab allows the user to view and compare model results, and to produce charts and tables with the option to export model results for further analysis. |

There are three input files that are used every time the model is run:

- Instruction file: This file contains the code that sets up and operates the model. It offers a much wider range of options for potential scenarios but does require a basic knowledge of the IDIOM scripting language that is used. Advanced users typically work extensively with the instruction file.
- Scenario file: This contains a set of policy inputs, including carbon taxes and energy taxes, that can be modified easily without any programming.
- Assumptions file: This contains exogenous assumptions such as commodity prices, world growth rates, state tax rates and government spending. These can also be modified easily without any programming required.

A set of baseline inputs is provided: EnForecast.idiom (instruction file), Assumptions.idiom (assumption file) and BaseScen.idiom (scenario file).

It is recommended not to delete the baseline input files, but to instead duplicate these files, make changes to the duplicates and save them under different names for scenario analysis.

Running the It is recommended to have a set of baseline results first for comparison with future scenario results. To run the baseline:

- 1. Go to Running the model tab.
- 2. Select the default baseline inputs from the list: EnForecast.idiom (instruction file), Assumptions.idiom (assumption file) and BaseScen.idiom (scenario file).
- 3. Type in a name to be given to the output of this run e.g. 'baseline'.

4. Click 'run the model' button and wait until it finishes.

Setting up To set up and run scenarios after the baseline:

scenarios

- 1. Go to the relevant tab to make the change (assumptions, scenarios or instructions)
- 2. Make a copy of the default input file by pressing the duplicate button and entering a new file name for it.
- 3. Make changes to the new file.
- 4. Click save once finished.
- 5. Follow step 1-4 of running the baseline above but make sure to select the relevant input files and provide a different name for results file.

Alternatively, steps 2 to 4 can be carried out outside the Manager by making a copy of the original input files and editing them manually using a standard text editor software package (e.g. Windows Notepad).

Note: output files are automatically saved to the C:\e3-india\output folder.

Figure 1.3: Image of a model scenario

Every time the user runs the model, three run sequences are automatically called (see command lines below). These lines are the model executables. The model runs over history first (to e.g. generate lagged variables), the forecast period (from the EnForecast script) and in a separate routine to print out the results (from the Dan1 script).

Figure 1.4: The three stages of running the model

The display box summarises key model variables as the model solves for each year of solution. It provides a quick overview of the model solution for all Indian states while the model is running. A full set of the model results can be accessed once the model has finished running.

Figure 1.5: Display when the model is running

Table 1.2: The variables displayed while the model is running

Once the model finishes running, the output from the model run is saved in the C:\E3-India\Output folder. The output file is saved under a text (.mre) format which the Manager software translates into graphical format, allowing the user to inspect the model results in detail.

The Manager software automatically lists all the files with a .mre extension in the C:\E3-India\Output folder and users can select which sets of results to display.

To select the results to display go to the Model Results tab. If the latest model run does not appear in the list, refresh the page as you would normally do in the internet browser. Select the results from the model runs that you wish to inspect and click on the 'Enable frontend' button.

| E3-India | Introduction | Instructions | Scenarios | Assumptions | Variables | Running the model Model results |
|------------|------------------------------|--------------|-----------|-------------|-----------|---------------------------------|

| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | ~ | |
| Enable fro | ntend | | | | | |
| | | | | | | |

To view the model results, select the relevant scenario(s), variable and dimensions to display.

Figure 1.7: Example of model output

To compare scenario results against a baseline, select the baseline in the baseline drop down list (this can be any file). Choose the scenario, variable and dimensions to display.

Users can choose whether to view results in levels, absolute differences from baseline, relative difference from baseline, or year-on-year growth by selecting the relevant options in the bottom-left corner.

Additionally, users can select more than one sector or state to display simultaneously on the chart (by shift-clicking or control-clicking). There is an option to sum the dimensions selected, which is useful for checking aggregate results.

Figure 1.8: Example of comparing results against baseline

To export results, select 'Show a table of data' and a table containing data will appear at the bottom of the page. Click 'download data as csv' to export this table to .csv file. Alternatively, users can copy and paste the table to a spreadsheet package manually.

Users can browse through the full set of results from a model run. To rerun the model, return to the previous tabs. To look at the results from a different set of model runs, click on *'reload data'* button.

2 Model Inputs and Outputs

2.1 Introduction

This chapter describes E3-India's main model inputs and outputs. The following sections describe the main inputs that the model relies on, including data and econometric parameters. The final part of this chapter describes the format of the main model outputs.

2.2 Data inputs

Introduction to the model data are the most important single input to E3-India. A lot of effort is put into ensuring that the model data are accurate and consistent to the maximum degree possible.

The following databanks are used to store the data:

- T historical time-series data
- F processed baseline forecast (see Section 4)
- X cross-section data, including input-output tables and equation parameters
- E energy balances, prices and emissions
- U classification titles

One other databank is used for model operation:

 S – holds the calibration factors to match the baseline forecast (see section 4 of this chapter)

E3-India's data requirements are extensive and specific. All data must be processed so that they are in the correct classifications and units. Gaps in the data must be filled (see below). All data processing is carried out using the <u>Oxmetrics software package</u>.

Time-series It is a substantial exercise to create and maintain the time series of economic data data. The main dimensions involved are:

- indicator
- states
- sector
- time period (annually from 1993)

In addition, indicators that are expressed in monetary units have constant and current price versions. Cambridge Econometrics therefore puts a large amount of resources into processing the time-series data.

The raw data are gathered from the sources described below and stored on the T databank. The model uses official sources as much as possible. It is often necessary to combine data sets to fill out gaps in the data and to estimate remaining missing values (see below).

The main A 'V' at the start of the name indicates a current price value; otherwise the indicators indicator is expressed in constant prices (2011 rupees). The main indicators with full sectoral disaggregation are:

- QR/VQR output (constant and current price bases)
- YVM/VYVM, YVF/VYVF GVA at market prices and factor cost
- KR/VKR investment
- CR/VCR household expenditure (by product)
- GR/VGR government final consumption (by category)
- QRX/VQRX exports
- QRM/VQRM imports
- YRE employment
- YRLC labour costs (current prices)

There are also time series for population (DPOP) and labour force (LGR), disaggregated by age and gender.

In addition, there are several macro-level time series that are used in the modelling. These include GDP, household incomes, tax and interest rates and the unemployment rate. They are also collected on an annual basis, starting from 1993.

Data sources for
E3-India'sTable 2.1 gives a summary of the data sources for economic variables used in
the E3-India model. Most data are collected from original sources and
processed by Indian national account data experts. Database construction was
a major task. Full detailed data documentation is given in Appendix C.

The data must be consistent across states and in the same units. For monetary data, the rupee is used.

| Variable | Source |

Values and price
indices in E3-
IndiaThe general principle adopted in E3-India is that variables are defined in the
currency unit appropriate for the use of the variable. This usually means that the
units of measurement follow those in the data source. The principle of
comparability is taken to imply that most current values are measured in millions
of rupees and most constant values in millions of rupees at 2011 prices.

The price indices are calculated by dividing current by constant values in rupees.

Cross-sectional data By cross-sectional data we mean data that are not usually available in timeseries format. Historically, this has meant input-output tables. Other crosssectional data include converters between model classifications that do not normally change over time.

Input-output tables in E3-India There are no input-output data publicly available at state levels. However, state level input-output is crucial in the E3-India model as it is used to distinguish different economic characteristic between states and provide linkages between local industries. Our Indian national account expert spent great effort in putting together input-output flows information at state level from raw data sources. For full documentation on how the IO tables at state level were constructed, including sources, please see Appendix C.

Input-output flows are converted to coefficients by dividing the columns by industry output. These coefficients give the number of units of input required to produce one unit of output.

Energy and State-level energy and emissions data for E3-India come from various sources. **emissions data** Where state-level data are not available, national data are used as proxies.

| Variable | Source |
|---------------------------------------|---|
| Coal consumption | MOSPI Installed capacity, generation and consumption 2007-2013 |
| Oil consumption | Indian Petroleum and Natural Gas statistics (Ministry of Petroleum & Natural Gas) |

Correcting for missing data points

The team at Cambridge Econometrics has developed a software package to fill in gaps in any of the E3-India time series. The approach uses growth rates and shares between sectors and variables to estimate missing data points, both in cases of interpolation and extrapolation. Some time series have specific rules for filling gaps in the data, but the general procedures are described here. The most straightforward case is when the growth rates of a variable are known and so the level can be estimated from these growth rates, as long as the initial level is known. Sharing is used when the time-series data of an aggregation of sectors are available but the individual time series is not. In this case, the sectoral time series can be calculated by sharing the total, using either actual or estimated shares.

In the case of extrapolation, it is often the case that aggregate data are available but sectoral data are not; for example, government expenditure is a good proxy for the total growth in education, health and defence spending. A special procedure has been put in place to estimate the growth in more disaggregated sectors so that the sum of these matches the known total, while the individual sectoral growth follows the characteristics of each sector. Interpolation is used when no external source is available, to estimate the path of change during an interval, at the beginning and end of which data are available.

Under different assumptions, time-series forecasts are created for each country and each aggregated variable: consumption, employment, GDP, trade and investment.

Naming conventions

E3-India's software limits model variables to four character names. These characters are typically used to identify first the dimensions of the variable (excluding time, which is a dimension for all the variables) and then the indicator. In particular, Q indicates disaggregation by product, Y by industry, F by energy (fuel) user and R by region. If a variable name starts with P then it usually indicates a price. S and 0 can be used to identify sums.

These conventions are used in the data processing and in the model itself. Some examples of common variables names are provided below:

- QR: (Gross) output by product and by region
- YR: (Gross) output by industry and region
- YRE: Employment by industry and region
- YRW: Wage rates by industry and region
- YRVA: Gross value added by industry and region
- CR: Consumption by consumption category and region
- PCR: Consumption prices by category and region
- RSC: Total consumption by region
- PRSC: Aggregate consumer price by region
- KR: Investment by investment category and region
- FR0: Total energy consumption by energy user and region
- FRET: Electricity consumption by energy user and region
- FCO2: CO2 emissions by energy user and region
- RCO2: CO₂ emissions by region

2.3 Econometric parameters

The econometric techniques used to specify the functional form of the equations are the concepts of cointegration and error-correction methodology, particularly as promoted by Engle and Granger (1987) and Hendry et al (1984).

In brief, the process involves two stages. The first stage is a levels relationship, whereby an attempt is made to identify the existence of a cointegrating relationship between the chosen variables, selected on the basis of economic theory and a priori reasoning, e.g. for employment demand the list of variables contains real output, real wage costs, hours-worked, energy prices and the two measures of technological progress.

If a cointegrating relationship exists then the second stage regression is known as the error-correction representation, and involves a dynamic, first-difference, regression of all the variables from the first stage, along with lags of the dependent variable, lagged differences of the exogenous variables, and the error-correction term (the lagged residual from the first stage regression). Due to limitations of data size, however, only one lag of each variable is included in the second stage.

Stationarity tests on the residual from the levels equation are performed to check whether a cointegrating set is obtained. Due to the size of the model, the equations are estimated individually rather than through a cointegrating VAR. For both regressions, the estimation technique used is instrumental variables, principally because of the simultaneous nature of many of the relationships, e.g. wage, employment and price determination.

Software used E3-India's parameter estimation is carried out using a customised set of software routines based in the Ox programming language (Doornik, 2007). The main advantage of using this approach is that parameters for all sectors and countries may be estimated using an automated approach.

The estimation produces a full set of standard econometric diagnostics, including standard errors and tests for endogeneity.

Estimation A list of equation results can be made available on request and parameters are stored on the X databank. For each equation, the following information is given:

- summary of results
- full list of parameter results
- full list of standard deviations

2.4 Baseline forecast

Overview The E3-India model can be used for forming a set of projections, but it is usually used only for policy analysis. Policy analysis is carried out in the form of a baseline with additional policy scenarios, with the differences in results between the scenarios and the baseline being attributed to the policy being assessed.

This section describes how the baseline is formed.

Role of the baseline Usually results from E3-India scenarios are presented as (percentage) difference from base, so at first it may appear that the actual levels in the baseline are not important. However, analysis has shown that the values used in the baseline can be very important in determining the outcomes from the analysis. For example:

- If a scenario has a fixed emission target (e.g. 20% below 2005 levels) then the baseline determines the amount of work that must be done in the scenario to meet the target.
- If a scenario adds a fixed amount on to energy prices, then baseline energy prices determine the relative (percentage) impact of that increase.

It is therefore important to have a baseline that does not introduce bias into the scenario results. A common requirement of E3-India analysis is that the baseline is made to be consistent with official published forecasts. Since we do not have access to state-level economic and energy projections, the E3-India baseline is calibrated to national projections from the World Energy Outlook (IEA, 2015). State-level projections have been set to match.

Methodology for calibrating The first stage in matching the E3-India projections to a published forecast is to process these figures into a suitable format. This means that the various dimensions of the model must be matched, including:

- geographical coverage (i.e. each state and territory)
- annual time periods
- sectoral coverage (including fuels and fuel users)
- National Accounts entries

CE uses the Ox software for carrying out this process, and saves the results on to the forecast databank, F.db1.

The next stage is to solve the model to match the results on the forecast databank. This is referred to as the 'calibrated forecast'. In this forecast, the model solves its equations and compares differences in results to the figures that are saved on the databank. The model results are replaced with the databank values but, crucially, the differences are stored and saved to another databank, S.db1. These are referred to as 'residuals' although the meaning is slightly different to the definition used in econometric estimation.

Endogenous The final stage is the 'endogenous solution' in which the model equations are baseline and scenarios outcome should be the same as for the calibrated forecast, although in practice there are calibration errors so it is not an exact match.

The key difference, however, is that inputs to the endogenous baseline may be changed in order to produce a different outcome (as opposed to the calibrated forecast where the model would still match databank values). The final outcome is thus a baseline forecast that matches the published projections, but which can also be used for comparison with scenarios.

Operational example of forecast, E3-India predicts a value of 100bn rupees, but the published forecast suggests 101bn rupees then the calibrated forecast will estimate a residual of 1.01 (i.e. 101/100).

If we then test a scenario in which consumption increases by 2% in this year, the model results will be 100bn rupees (endogenous baseline) and 102bn rupees (scenario). These will be adjusted (multiplied) by the residual to become 101bn rupees and 103.02bn rupees.

When these results are presented as percentage difference from base, the figure that is reported is still 2% (103.02/101), so the calibration does not affect directly the conclusions from the model results.

When are resultsIn this example, there is no impact on the results relative to baseline from the
calibration?influenced by
calibration?In this example, there is no impact on the results relative to baseline from the
calibration exercise. This is typically true for any log-linear relationship within
the model structure, as the calibration factors are cancelled out when calculating
differences from base.

However, there are relationships in the model that are not log-linear, most commonly simple linear factors. These include the construction of energy prices but also identities for GDP and for (gross) output, and the calculation for unemployment (as labour supply minus demand).

For example, if the calibration results in higher trade ratios in a certain country, then the effects that trade impacts have on GDP will increase in the scenarios.

It is therefore important that the baseline provides a reasonable representation of reality, otherwise it is possible to introduce bias into the results.

2.5 Other model data inputs

In the current version of the model there are two additional text files that are used as inputs (asides from the instruction file, see Chapter 2). These are the assumptions file and the scenario file, both of which can be modified by the model user.

The reason for having these inputs as text files rather than databank entries is that it allows easy manipulation, including through the Manager software (see Section 1.2). No programming expertise is therefore required to make the changes.

Assumptions file The assumptions file contains basic economic information that is necessary for any model run. It consists mainly of exogenous model variables that are set by the model user.

The nature of the Fortran read commands means that the structure of the assumptions text files is very rigid, for example with the right number of white spaces (not tabs) and decimal places required for each entry.

The assumptions files cover the period 2000 to 2050 although historical values will get overwritten by the data stored on the model databanks and the last year of the model is 2035.

Commodity At the top of the assumption file is a set of global commodity prices, with a focus prices on the energy groups that are covered by the model classifications. The figures are annual growth rates, in percentage terms.

Other world Also at the top of the assumption file there is a set of twelve other countries' GDP assumptions that form demand for Indian exports. The E3-India model assumes that rates of growth in the rest of the world are exogenous, matching the numbers in the assumptions file. The figures are annual growth rates, in percentage terms.

National and This is followed by a set of assumptions that are specific to each state. They *regional* are:

assumptions

policies

- Market exchange rate (not used)
- Long-run interest rate (same as national rate)
- Short-run interest rate (same as national rate, only used for comparative purposes)
- Change in government final consumption, year on year
- % of government consumption spent on defence, education and health
- Standard VAT rate
- Aggregate rate of direct taxes
- Average indirect tax rates
- Ratio of benefits to wages (giving implicit rate)
- Employees' social security rate
- Employers' social security rate
- Scenarios file The scenario file contains a set of policy inputs that relate to basic model scenarios (see examples in Chapter 3). It can also be modified through the model Manager. Most of the policies in the scenario files are absent in the baseline. Policy inputs in the scenario file are categorised to three main groups: CO₂ emissions policies, energy policies and options to recycle the revenue generated from market-based instruments.

CO₂ emissions The following CO₂ emissions policies are available in the scenarios file:

- annual CO₂ tax rate, rupees per tonne of carbon
- switches to include different energy users in the policies
- switches to include different fuel types in the policies

Energy policies The following energy policies are available in the scenario file:

- annual energy tax rate, rupees per toe
- switches to include different users in policies
- switch to include different fuel types in policies
- households implied price of electricity subsidies

Revenue The scenario file includes options to recycle automatically the revenues *recycling options* generated from carbon taxes and energy taxes (so that government balances remain unchanged). There are three options in the scenario file for how the revenues are recycled:

- to lower employers' social security contributions, switch 0<X<1: 1=all, 0= none
- to lower income tax rates, switch 0<X<1: 1=all, 0=none
- to lower VAT rates, switch 0<X<1: 1=all, 0= none

These revenue recycling options do not differentiate sources of revenues. The model automatically sets the revenues to be recycled from the policies so that they are overall 'revenue neutral'. Specific values for offsetting tax reductions can be entered through the assumption file discussed above.

2.6 Model outputs

Overview The model produces relatively few results automatically. It instead stores results internally so that they can be accessed separately. The separation of model solution, (1) writing the results year by year to a large file (the 'dump'), and then (2) accessing this file to generate time series of results, is necessary because of software constraints and the logic of the model.

Because of the scale of the solution, the model does not hold all the time series of each variable, but only the current and past values necessary for the current year's solution; this reduces the storage requirements dramatically (one year plus lags instead of up to 50 years of values). At the completion of each year's solution, the solved values of most variables are written to the dump where they may be later accessed.

Data analysis files The files that access the model results are called data analysis files. They are instruction files that are run after the model has finished solving (see Chapter 2).

The file produced contains matrix output. These files are designed as inputs to further processing, for example by other programming languages, or interpretation by the model manager software. They appear in the output directory with a '.MRE' extension.

The data analysis files must start with a RESTART command with a year that matches the PUT ALL statement in the IDIOM instruction file (usually the first year of solution). A SELECT command then determines the output stream and format:

• SELECT OUTPUT 7 CARDS – MRE output

The syntax is then relatively straight forward. The VALUE command is followed by the variable name, start year and end year to give a table in time series format. The CHANGE command gives the equivalent output as annual growth rates. For variables with two dimensions (excluding time) it is necessary to say which column is required. So, for example, the command:

• VALUE CR(?:03) 2013 2020

would give a time series for household consumption in Assam (region 3) between 2013 and 2020. The following command will print out results for all states:

• VALA CR(?:01) 2013 2020

Other model outputs The other model outputs are created for diagnostic purposes. A small text file (diagnostics.mre) is created automatically, which contains summary information about whether the model has solved and, if not, which equation caused the breakdown in solution. A longer 'verification' text file contains automatically generated outputs from the model, including warnings and possible nonconvergences in the solution (see Section Error! Reference source not found.), which can be returned to Cambridge Econometrics to assist with problems in solution. The verification files are by convention given names that start with the letter Q and are stored in the verification folder in the output directory.

3 The E3-India Test Scenarios

3.1 Introduction

We provide a set of pre-loaded model input files that were used in testing the E3-India. Table 3.1 provides an overview.

| Table 3.1: Overview of | f example scenarios |
|------------------------|---------------------|
|------------------------|---------------------|

| Run | Description | Instruction file | Assumptions file | Scenario file |
|----------|---|------------------|------------------|---------------|
| Baseline | E3-India baseline | EnForecast | Assumptions | BaseScen |
| S1 | Exogenous investment | EnTest1 | Assumptions | BaseScen |
| S2 | Income tax | EnForecast | Assump1 | BaseScen |
| S3 | Energy tax | EnForecast | Assumptions | Scen1 |
| S4 | Carbon tax | EnForecast | Assumptions | Scen2 |
| S5 | S4+ revenue recycling (employers' SSC) | EnForecast | Assumptions | Scen3 |
| S6 | S4+ revenue recycling (income tax) | EnForecast | Assumptions | Scen4 |
| S7 | S4+ revenue recycling (VAT) | EnForecast | Assumptions | Scen5 |
| S8 | Energy efficiency | EnTest4 | Assumptions | BaseScen |
| S9 | Feeds-in-Tariff | EnTest2 | Assumptions | BaseScen |
| S10 | Renewable subsidies | EnTest3 | Assumptions | BaseScen |
| S11 | Exogenous oil price | EnForecast | Assump2 | BaseScen |
| S12 | Removing Electricity Price Subsidies to households | EnForecast | Assumptions | Scen6 |

To run the scenarios, select the pre-loaded input files accordingly in the options in **Running the model** tab. Then give the output file names for each run (e.g. S1,S2,... S11,S12). Click the run model button.

Please refer to main E3-India -Testing Scenarios document for more information.

Note making use of text editors The input files that appear in the E3-India Manager software are text files that can be edited outside the E3-India Manager software environment using any text editor software. This may be preferred if the input requirements are complex. Another useful tip is to use some text editor software to highlight the differences of the two input files.

However it must be noted that, if editing these files outside the Manager software, the model input.idiom files require text formatting to be exactly the same as the default file provided.

Test scenario 1: Investment 3.2

Exogenous investment in 18. Other business Services sector from 2016 onward Scenario (10% of existing investment) description

| Model inputs | Variable | Description | Unit | Input file |
|--------------|-------------|---------------------------------------|--------------|-------------------|
| | KRX(18,all) | Exogenous | 2011 million | EnTest1 (Idiom |
| | | investment by sector and by region | rupees | instruction file) |

Scenario main impacts

| Im | pa | CL |
|----|----|----|
| | | |

| Variable | Description | Impacts (compared to BAU) | | |
|-----------------------------|---------------------|---|--|--|
| RSK (KR*) | Investment | Increase | | |
| RSQ (QR*) | Industry output | Increase | | |
| REMP (YRE*) | Industry employment | Increase overall but some decrease (substitution effect between capital and labour) | | |
| RSX (QRX*) | Industry export | Increase (demand from other regions + technology impacts) | | |
| RSM (QRM*) | Industry import | Increase (demand for other region goods/services) | | |
| * denotes sectoral variable | | | | |

3.3 Test scenario 2: Income tax

Scenario description Increase average income tax rate in region 1 Andhra Paresh from 23% to 30% from 2017 onward (note further income tax testing for all regions are included in another test scenario – using revenues from carbon tax to reduce income tax in all regions).

| Model inputs | Variable | Description | Unit | Input file |
|--------------|-----------------|-----------------|--------------|-------------------|
| | RDTX | Average direct | % of wages | Assump1 |
| | (11 TAX_DIRECT) | income tax rate | and salaries | (assumption file) |
| | | | | |
| | | | | |
| | | | | |

| Scenario main impacts | Variable | Description | Impacts (compared to BAU) |
|--------------------------|-----------------------------|--|--|
| | RRPD | Gross real disposable income (i.e. income after tax) | Decrease |
| | RSC | Consumer spending | Decrease |
| | GDP | GDP | Decrease |
| | REMP (YRE*) | Employment | Decrease |
| | RSQ (QR*) | Industry output | Decrease (especially services sector which are highly related to consumer spending) |
| | * denotes sectoral variable | • | |

3.4 Test scenario 3: Energy tax

Scenario Tax of 400 rupees per tonne of oil equivalent to all energy users of all fuels. **description**

Model inputs

| Variable | Description | Unit | Input file |
|----------|-------------------------------|-------------------|------------------|
| RTEA | Energy tax rate 2001- 2035 | Rupees/toe | Scen1 (scenario) |
| FEDS | Switch for fuel user coverage | 1 = full coverage | Scen1 (scenario) |
| JEDS | Switch for fuel type coverage | 1 = full coverage | Scen1 (scenario) |

Scenario main Variable Description Impacts (compared to BAU) impacts RFU (FR0*) Total fuel demand Decrease **FRET*** Electricity demand Decrease (substitution with other fuels) Coal demand **FRCT*** Decrease (substitution with other fuels) **FROT*** Oil demand Decrease (substitution with other fuels) FRGT* Gas demand Decrease (substitution with other fuels) RCO2 (FCO2) CO2 emissions Decrease PRSC (PCR*) Average consumer price Increase (due to tax) index RSC (CR*) Consumer spending Decrease (less disposable income) **RSX (QRX*)** Export Mostly decrease (from higher energy price but relative to other states so there are competitiveness effects from internal trade) RSM (QRM*) Import Mostly decrease from lowered domestic demand and imports of energy RGDP GDP +/- depending on scale of import reduction (improvement to GDP) * denotes sectoral variable

Cambridge Econometrics

3.5 Test scenario 4: Carbon tax

Scenario description Tax of 400 rupees per tonne of carbon (note not CO₂) to all energy users of all fuels. Note assuming no revenue recycling. All revenues are used to reduce government deficit.

| Model inputs | Variable | Description | Unit | Input file |
|--------------|----------|-------------|------------------|------------------|
| | RTCA | Carbon tax | Rupees/tonne | Scen2 (scenario) |
| | | rate, 2001- | of <u>carbon</u> | |
| | | 2035 | | |
| | FEDS | Switch for | 1 = full | Scen2 (scenario) |
| | | fuel user | coverage | |
| | | coverage | | |
| | JEDS | Switch for | 1 = full | Scen2 (scenario) |
| | | fuel type | coverage | |
| | | coverage | | |

Scenario main Variable Description Impacts (compared to impacts BAU) RCO2 (FCO2) CO2 emissions Decrease RFU (FR0*) Total fuel demand Decrease FRET* Electricity demand +/- (substitution with other fuels) Coal demand **FRCT*** Decrease (substitution with other fuels) **FROT*** Oil demand Decrease (substitution with other fuels) FRGT* Gas demand Decrease (substitution with other fuels e.g. coal to gas) MJEF* Fuels demand by PG Fossil fuels decrease MEWG* Power sector generation Fossil fuels decrease/ by technologies possibly small increase in renewable shares but not drastic due to small CO₂ tax Localised costs of **METC*** Fossil fuels costs increase electricity as seen by investors by technologies (including carbon costs + policies) PYH(9,all)* Electricity price (sector 9) Increase PRSC (PCR*) Average consumer price Increase (due to tax and index higher electricity price) RSC (CR*) Consumer spending Decrease (less disposable income) RSX (QRX*) Export Mostly decrease (from higher energy price but relative to other states so there are competitiveness effects from internal trade)

| RSM (QRM*) | Import | Mostly decrease from lowered domestic demand and imports of energy |
|-------------------------|--------|--|
| RGDP | GDP | +/- depending on scale of import reduction (improvement to GDP) |
| * denotes sectoral vari | able | |

Figure 3.2: The impact of the carbon/energy tax on fuel use, CO_2 emissions and industrial employent

9.5 Test scenario 5: Carbon tax+revenue recycling (employers' social security contribution)

Scenario description

Same tax as previously (400 rupees per tonne of carbon) to all energy users of all fuels. All revenues from carbon tax used to reduce employers' social security contribution within the region.

| Model inputs | Variable | Description | Unit | Input file |
|--------------|----------|-----------------|------------------|------------------|
| | RTCA | Carbon tax | Rupees/tonne | Scen3(scenario) |
| | | rate, 2001- | of <u>carbon</u> | |
| | | 2035 | | |
| | FEDS | Switch for fuel | 1 = full | Scen3 (scenario) |
| | | user coverage | coverage | |
| | JEDS | Switch for fuel | 1 = full | Scen3 (scenario) |
| | | type coverage | coverage | |
| | RRTE | Proportion of | 1 = 100% | Scen3 (scenario) |
| | | energy tax and | | |
| | | carbon tax to | | |
| | | reduce | | |
| | | employers'SSC | | |
| | | by | | |

Scenario main In addition to the carbon tax scenario.

impacts

| Variable | Description | Impacts (compared to the carbon tax with no revenue recycling scenario) |
|-----------------------------|----------------------------|--|
| RCTT | Total revenues from carbon | Increase (tax rate x CO2 |
| | tax (m rupees) | emissions) |
| RERR | Employers social security | Decrease |
| | contribution rates | |
| REMP (YRE*) | Employment | Increase (direct impact |
| | | from lowering labour costs |
| | | to firms) |
| RGDP | GDP | Increase |
| RSC (CR*) | Consumer spending | Increase |
| RWS (YRWS*) | Total wages and salaries | Increase |
| RRDP | Real disposable income | Increase |
| РҮН | Industry prices | Decrease (reduction in |
| | | labour unit cost) but not all |
| | | costs will pass through to |
| | | final price |
| * denotes sectoral variable | | |

Test scenario 6: Carbon tax+revenue recycling (income tax) 3.6

Scenario Same tax as previously (400 rupees per tonne of carbon) to all energy users of description all fuels. All revenues from carbon tax used to reduce direct tax (income tax) within the region.

| Model inputs | Variable | Description | Unit | Input file |
|--------------|----------|---------------|------------------|------------------|

| | | coverage | | |
| | JEDS | Switch for | 1 = full | Scen4 (scenario) |
| | | fuel type | coverage | |
| | | coverage | | |
| | RRTR | Proportion | 1 = 100% | Scen4 (scenario) |
| | | of energy | | |
| | | tax and | | |
| | | carbon tax | | |
| | | to reduce | | |
| | | direct tax by | | |

Scenario main In addition to the carbon tax scenario.

impacts

| Variable | Description | Impacts (compared to the carbon tax with no revenue recycling scenario) |
|-----------------------------|---|--|
| RCTT | Total revenues from carbon tax (m rupees) | Increase (tax rate x CO2 emissions) |
| RDTR | Direct tax rates | Decrease |
| RRDP | Real disposable income (income after tax) | Increase |
| RSC (CR*) | Consumer spending | Increase |
| RGDP | GDP | Increase |
| REMP (YRE*) | Employment | Increase (secondary impact from higher GDP) |
| * denotes sectoral variable |) | |

Test scenario 7: Carbon tax+revenue recycling (VAT) 3.7

Scenario Same tax as previously (400 rupees per tonne of carbon) to all energy users of description all fuels. All revenues from carbon tax used to reduce VAT within the region.

Model inputs

| Variable | Description | Unit | Input file |
|----------|-------------|------------------|------------------|
| RTCA | Carbon tax | Rupees/tonne | Scen5(scenario) |
| | rate, 2001- | of <u>carbon</u> | |
| | 2035 | | |
| FEDS | Switch for | 1 = full | Scen5 (scenario) |
| | fuel user | coverage | |

| JEDS | Switch for | 1 = full | Scen5 (scenario) |
| | fuel type | coverage | |
| | coverage | | |
| RRVT | Proportion | 1 = 100% | Scen5 (scenario) |
| | of energy | | |
| | tax and | | |
| | carbon tax | | |
| | to reduce | | |
| | VAT by | | |

Scenario main In addition to the carbon tax scenario.

impacts

| Variable | Description | Impacts (compared to the carbon tax with no revenue recycling scenario) |
|-----------------------------|----------------------------|--|
| RCTT | Total revenues from carbon | Increase (tax rate x CO2 |
| | tax (m rupees) | emissions) |
| RSVT | VAT rates | Decrease |
| PRSC (PCR*) | Consumer price index | Decrease |
| RSC (CR*) | Consumer spending | Increase |
| RGDP | GDP | Increase |
| REMP (YRE*) | Employment | Increase (secondary |
| | | impact from higher GDP) |
| * denotes sectoral variable | | |

3.8 Test scenario 8: Energy efficiency (savings + investment)

Scenario
 10% energy savings in the use of coal by manufacturing sector in all regions.
 Manufacturing investment increase approximately \$1m (60 m rupees) per 6,000 toe (source: estimated from IEA WEIO and WEO publications). Investment paid for by manufacturing (increase in cost to the sector).

| Variable | Description | Unit | Input file |
|-------------|---|---|--|
| FRCH(3,all) | Exogenous change in coal demand by manufacturing (fuel user 3) | Thousand TOE | EnTest4.idiom (IDIOM Instruction file) |
| KRX(8,all) | Exogenous change in investment by manufacturing sector (industry 8) | 2011 m rupees | EnTest4.idiom (IDIOM Instruction file) |
| YRUX(8,all) | Exogenous increase in costs to manufacturing (get added to total unit cost) | Entered as m rupees and get converted to unit cost in model | EnTest4.idiom (IDIOM Instruction file) |

Scenario main impacts

Model inputs

| Variable | Description | Impacts (compared to |
|-----------------------------|------------------------|-----------------------|
| | | BAU) |
| FRCT | Coal demand | Decrease |
| FR0 | Total energy demand | Decrease |
| FCO2 | CO2 | Decrease |
| RSK (KR*) | Investment | Increase |
| RGDP | GDP | Increase |
| YRUC* | Unit costs of industry | Increase |
| PYH* | Industry price | Increase by less than |
| | | costs |
| Other++ | | |
| * denotes sectoral variable | | |

Figure 3.3: The main economic interactions of energy efficiency

3.9 Test scenario 9: Feeds-in-tariff

Scenario Feed-in-tariff for renewables technologies in FTT-power: -110% difference between levelized costs and electricity price.

Technology included: Tidal (15), Large Hydro(16), Onshore(17), Offshore(18), CSP(20) note Solar PV (19) already have FIT in the baseline.

Example

LCOE of solar is \$140/MWh, Electricity price is around \$50/MWh FIT is (140-50) *-1.1 = - \$99/MWh Cost to investor become 140-99 = \$41/MWh making small profit (\$50-\$41 = \$9/MWh).

Note that FIT rate of -110% doesn't make all technologies profitable depending on difference between costs and price of that technology

| Model inputs | Variable | Description | Unit | Input file |
|--------------|----------|--|---|---|
| | MEFI | Feed-in-tariff by power technology by region | % difference between levelised cost and electricity price | EnTest2.idiom (IDIOM Instruction file) |

| impacts ME ME ME | Variable | Description | Impacts (compared to BAU) |
|------------------------|-------------|---|---|
| | METC* | Localised costs of electricity as seen by investors by technologies (including carbon costs + policies) | Decrease in technologies with FIT |
| | MEWK* | Power sector capacities by technologies by region | Renewable shares increase (but there will be substitution due to differences in final LCOE) |
| | MEWG* | Power sector generations by technologies by region | Renewable shares increase (but there will be substitution due to differences in final LCOE) |
| | MWIY | Power sector investment in new capacity | Renewable increase (but fossil fuels could decrease) |
| | MJEP*/PFRE* | Price of energy/Price of electricity | Electricity price increase to pay for FIT |
| | FRET* | Electricity demand | Reduce from higher electricity price |

| PRSC | Consumer price index | Increase from higher electricity price |
|--------------------------|----------------------|---|
| RSC (CR*) | Consumer spending | Decrease |
| RSK (KR*) | Investment | Higher investment by electricity sector (feedback from FTT) |
| RGDP | GDP | +/- depending on scale of RSC and RSK impacts |
| Other++ | | |
| * denotes sectoral varia | able | |

3.10 Test scenario 10: Renewable subsidies

ScenarioSubsidies for renewables technologies in FTT-power: 50% of investment costsdescriptionof technologies

Technology included: Tidal (15), Large Hydro(16), Onshore(17), Offshore(18), Geothermal(21)

Note(s): we assumed government paid for the subsidies but not raise taxes in response (i.e. through bigger budget deficit). This assumption can easily be change to achieve revenue neutrality.

| Model inputs | Variable | Description | Unit | Input file |
|--------------|----------|--------------|------------|--|
| | MEWT | FTT | % of | EnTest3.idiom (IDIOM Instruction file) |
| | | subsidies by | investment | |
| | | power | cost of | |
| | | technology | technology | |
| | | by region | | |

| Scenario main impacts | Variable | Description | Impacts (compared to BAU) |
|--------------------------|--------------|---|--|
| | METC* | Localised costs of electricity as seen by investors by technologies (including carbon costs + policies) | Decrease in technologies with subsidies |
| | MEWK* | Power sector capacities by technologies by region | Renewable shares increase (but there will be substitution due to differences in final LCOE) |
| | MEWG* | Power sector generations by technologies by region | Renewable shares increase (but there will be substitution due to differences in final LCOE) |
| | MWIY | Power sector investment in new capacity | Renewable increase (but fossil fuels could decrease) |
| | MJEP*/ PFRE* | Price of energy /Price of electricity | Electricity price decrease because of subsidies |
| | FRET* | Electricity demand | Higher from lower electricity price |
| | PRSC (PCR*) | Consumer price index | Decrease from lower electricity price (although average could be positive due to higher economic activity) |
| | RSC (CR*) | Consumer spending | Increase |
| | RSK (KR*) | Investment | Higher investment by electricity sector (feedback from FTT) |
| | RGDP | GDP | Increase from investment and possibly lower price |

| (but could be negative once we start changing assumption about revenue |
|--|
| neutrality) |

3.11 Test scenario 11: Exogenous oil price

Scenario
descriptionIncrease exogenous global oil price assumption – instead of growing at 3% pa
between 2016-2020 let assume it is growing at 4% pa instead.

Note(s): Global energy price assumptions are in pa growth rate and derived from the latest IEA World Energy Outlook publication (current policies scenario).

| Model inputs | Variable | Description | Unit | Input file |
|--------------|--------------------|--------------|-------|---------------------------------|
| | PMF | Price of | Index | Assump2.idiom (assumption file) |
| | (CPRICE_BRENT_OIL) | import | | |
| | | groups in \$ | | |
| | | (2005 | | |
| | | =1.00) | | |

| Scenario main impacts | Variable | Description | Impacts (compared to BAU) | |
|--------------------------|-----------------------------|----------------------------|-----------------------------|--|
| | PFRO* | Oil price by fuel users | Increase from higher Brent | |
| | | | oil price assumption | |
| | PFR0* | Average price of energy by | Increase as oil price | |
| | | users | increases | |
| | RFU (FR0*) | Total fuel demand | Decrease | |
| | FROT* | Oil demand | Decrease | |
| | RCO2 (FCO2*) | CO2 emissions | Decrease | |
| | RGDP | GDP | Increase or decrease | |
| | | | depending on which | |
| | | | impacts are larger – | |
| | | | reduction in oil imports or | |
| | | | impacts from higher price | |
| | | | on consumption | |
| | RSM (QRM) | Imports | Oil import decrease | |
| | RSC (CR) | Consumer spending | Decrease due to higher | |
| | | | price lead to reduction in | |
| | | | real disposable income | |
| | * denotes sectoral variable | | | |

3.12 Test scenario 12: Removing Electricity Price Subsidies to households

Scenario Removing electricity price subsidies for each State to look at impacts on various types of households.

Note- subsidy is treated as negative tax in E3_India so a scenario to remove electricity subsidies implies a positive electricity tax on household's consumption of electricity.

The E3_India's energy users' classification is

- 1 Power generation
- 2 Other transformation
- 3 Manufacturing
- 4 Transport
- 5 Households
- 6 Services
- 7 Agriculture
- 8 Non-energy used

For electricity use, the model includes modelling of electricity price subsidies to different household types. This provides results on household's income distribution from changes in electricity taxation and subsidies. The figure below demonstrates how income distributions, measured by changes in real disposable income by household groups, are affected from changes in electricity prices.

It should be noted that due to lack of time series data, the model doesn't include price-elasticity of electricity demand for each group types of households. Users need to work out the equivalent average electricity price increase for the whole households group and use these values as electricity tax on the household groups. The variable PEHS², electricity price subsidies by households, enables

² Baseline PEHS is estimated from a) electricity price per consumption unit by state <u>https://www.bijlibachao.com/news/domestic-electricity-lt-tariff-slabs-and-rates-for-all-states-in-india-in-</u> users to adjust the subsidy rates to provide distributional impacts (no feedback to the rest of the model).

| Model inputs | Variable | Description | Unit | Input file |
|--------------|----------|---|--|------------------|
| | RTEA | Energy tax rate 2001-2035 (5000 rupees/toe) | Rupees/toe | Scen6 (scenario) |
| | FEDS | Switch for fuel user coverage (only households) | 1 = full coverage | Scen6 (scenario) |
| | JEDS | Switch for fuel type coverage (only electricity) | 1 = full coverage | Scen6 (scenario) |
| | PESH | Households implied price of electricity subsidies (removed all subsidies in the baseline – set to 1 for all groups) | 1.00 = no subsidies, 0.8 = 20% subsidies | Scen6 (scenario) |

Scenario main impacts

| Variable | Description | Impacts (compared to BAU) | | |
|-----------------------------|---------------------------------------|--|--|--|
| FRET* | Electricity demand from households | Decrease | | |
| RFU (FR0*) | Total fuel demand | Decrease or there might be substitution between fuels | | |
| PRSC (PCR*) | Average consumer price index | Increase (due to electricity tax) | | |
| RSC (CR*) | Consumer spending | Decrease (less disposable income) | | |
| RGDP | GDP | Small decrease from reduction in consumer demand | | |
| SRRI* | Real disposable income by households | Household groups that are more vulnerable (e.g. low income) are worse off than other groups | | |
| * denotes sectoral variable | | | | |

^{2016.}html and b) household electricity consumption by states, quintiles and rural/urban

B.1 Assumption file

In the assumptions file there are two types of inputs, commodity prices and GDP in other parts of the world. Both are expressed as annual growth rates. The categories are:

- 02 CPRICE_FOOD_FEED prices for food and animal feed
- 03 CPRICE_WOOD prices for wood as a raw material
- 04 CPRICE_CONS_MIN prices for aggregates and other construction minerals
- 05 CPRICE_IND_MIN prices for minerals used for industrial purposes
- 06 CPRICE_FER_ORES prices for ferrous ores
- 07 CPRICE_NFER_ORES prices for non-ferrous ores
- 08 CPRICE_COAL coal prices
- 09 CPRICE_BRENT_OIL oil prices
- 10 CPRICE_GAS natural gas prices
- 11 CPRICE_OTHERS prices for other commodities

The countries for which GDP growth can be adjusted are India's main trading partners. Other countries are included in the final rest of world category.

B.2 Scenario file

The inputs in the scenarios file are:

| Input | Units | Dimensions | Definition |
|-------|---------|-------------------------|---|
| RTEA | Rup/toe | State x Year | Energy tax levied on energy consumption |
| RTCA | Rup/tC | State x Year | Carbon tax levied on CO2 emissions |
| FEDS | Share | Fuel User x State | Exemptions from RTCA and RTEA, 0 = exempt |
| JEDS | Share | Fuel x State | Exemptions from RTCA and RTEA, 0 = exempt |
| RRTE | % | State x Year | Carbon/energy tax revenues used to reduce employers' social contributions |
| RRTR | % | State x Year | Carbon/energy tax revenues used to reduce income taxes |
| RRVT | % | State x Year | Carbon/energy tax revenues used to reduce VAT |
| PESH | Share | Income Group x State | Implied subsidies to each group (1 = none) |

Other inputs (through the instructions files) Additional flexibility is added when using the instructions files. Some of the most commonly used inputs here are shown below.

- FRCH (fuel user by state) exogenous reduction in coal consumption, in thousands of tonnes of oil equivalent.
- FROH, FRGH, FREH exogenous reductions in oil, gas and electricity consumptions (same dimensions and units).
- KRX (sector by state) exogenous increase in investment, millions of rupees at 2011 prices.

Almost all the variables in E3-India can be shocked exogenously. For further information on this please contact the modelling team.
